Kp-Fonts

The JOHANNES KEPLER project

Release 3.34

Christophe Caignaert (inactive)
c.caignaert@free.fr

Save up your toner and the environment, use the "light" option,
it’s 20% toner less!

1 Kp-Fonts

1.1 What is Kp-Fonts?

Kp-Fonts provides a full set of fonts for LaTeX typesetting, including roman, sans-serif et fixed-width fonts, as well as a set of mathematics symbol fonts with, regular and bold, all the common symbols and all those of the ams and more...

The typical feature of these fonts is to have a basic and dynamic shape. For instance, look at the roman upright "a" glyphs:

<table>
<thead>
<tr>
<th>Kp-Fonts</th>
<th>Kp-light</th>
<th>CM</th>
<th>Palatino</th>
<th>Utopia</th>
<th>Times</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>a</td>
<td>a</td>
<td>a</td>
<td>a</td>
<td>a</td>
</tr>
</tbody>
</table>

The project is to provide a large set of options to customize your math or text typesetting.

This LaTeX package is distributed with a gpl licence.

Kp-Fonts doesn’t require any other font package and is fully compatible with amsmath and textcomp with the full option. Kp-fonts loads these two packages except if you use relative options.

You haven’t to load amsmath and textcomp packages

You can use the options of amsmath a option of kpfonts, except cmex10.

To use it, you just have to add \usepackage{kpfonts} in your document preamble, if necessary with the options described below.

Besides, the aim is to get a good compatibility with different sets of math font packages.

---

1This version prepared by Herbert Voß (hvoss@tug.org)
1.2 Text fonts

- The encodings \( \text{l1} \), \( \text{ot1} \) et \( \text{ts1} \) are fully available, except for the upper-case symbol \( \text{SS} \) in teletype fonts; if you use some accents, you have to work with \( \text{l1} \) encoding, \( \text{ot1} \) is present for historical compatibility;

- Roman fonts are available with upright, small caps (usual and large), italic, slanted, small caps slanted (usual and large) and oldstyle shape, all with regular, bold and bold extended weight;

- Sans-serif fonts are available with upright and slanted, small caps upright and slanted (usual and large) shape, and oldstyle all with regular, bold and bold extended weight;

- Teletypes fonts are available with upright and slanted shape, all with regular and bold weight;

The default weight is bold, not bold extended.

1.3 Math fonts

- The \( \text{\texttt{\textbackslash boldmath}} \) command is fully installed and Kp-Fonts doesn't need "poor man bold" glyphs;

- Kp-Fonts provides upright and slanted greeks: \( \alpha \beta \gamma \Gamma \Delta \) and \( \alpha \beta \gamma \Gamma \Delta \);

- \( \text{\texttt{\textbackslash mathbb}} \) provides \( \text{ABC} \), characters designed from capital upright roman;

- \( \text{\texttt{\textbackslash mathcal}} \) provides \( \text{ABC} \), slightly altered fonts from \( \text{cm} \);

- \( \text{\texttt{\textbackslash mathscr}} \), you get \( \mathcal{ABC} \), without any extra package; these letters are designed from traditional fonts;

- \( \text{\texttt{\textbackslash mathfrak}} \) provides \( \mathfrak{ABCabc} \), still from traditional fonts, altered to be more readable: read \( \text{CTAN} \) and \( \text{CTAN} \) in \texttt{www.ctan.org}!

- See the \( \text{\texttt{\textbackslash mathupright}}, \) or \( \text{\texttt{\textbackslash mathup}} \), alphabet in the \texttt{sf} math versions section.

2 Options

2.1 Main global options

- \texttt{\textbackslash light}: then, you use the light version of the fonts, in text and math mode. The metrics are the same. The display is not very good, but the print is fine if you like light fonts;
This text is typesetted with default fonts, and below you can see an example of the light fonts set, upright and italic, both regular and bold:

While the high-level font commands are intended for use in a document, the low-level commands...

While the high-level font commands are intended for use in a document, the low-level commands...

While the high-level font commands are intended for use in a document, the low-level commands...

While the high-level font commands are intended for use in a document, the low-level commands...

**fulloldstylenums**: equivalent to both `oldstylenums` and `oldstylenumsmath`;

**fulloldstyle**: equivalent to both `oldstyle` and `oldstylemath`;

**fullveryoldstyle**: equivalent to both `veryoldstyle` and `veryoldstylemath`.

### 2.2 Other global options

**nomath**: Kp-Fonts doesn't modify default mathematical fonts;

**notext**: Kp-Fonts doesn't modify default text fonts;

**nosf**: Kp-Fonts doesn't modify default sans serif fonts (text and math);

**nott**: Kp-Fonts doesn't modify default fixed width fonts (text and math);

**onlyrm**: equivalent to the last two options;

**noamsmath**: Kp-Fonts doesn't load `amsmath` package;

**notextcomp**: Kp-Fonts doesn't load `textcomp` package.

With both the two first and two last options, Kp-Fonts does nothing...

### 2.3 Text fonts options

These options affect only text fonts.

**lighttext**: "light" fonts are used in text mode.
oldstylenums: provides here oldstyle numbers by default.

A new command \classicstylenums allows you to get usual numbers in roman fonts.

Some examples, upright and italic, medium and bold:

- 0123456789!
- 0123456789!
- 0123456789!
- 0123456789!

oldstyle: provides here "Q", and oldstyle numbers by default.

With roman and sans-serif fonts, you get the old ligatures "&lt;" and "&gt;". Oldstyle also provides the small capital "q".

A new command \classicstylenums allows you to get usual numbers in roman fonts.

Some examples:

- Queer font, queer actual aesthetic!
- Queer font, queer actual aesthetic!
- Queer font, queer actual aesthetic!
- Queer font, queer actual aesthetic!
- Queer font, queer actual aesthetic!
- Queer font, queer actual aesthetic!

veryoldstyle: Same as the oldstyle option except the round "s" is replaced with the long "f".

You can get the round "s" using the ligature "s="", often used at the end of the words.

Example: \textit{costs=} gives "co\textit{sts}".

Obviously, there is no long "f" in smallcaps shape!

rmx then, you get six weights, with the corresponding fonts:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>light</td>
<td>1</td>
<td>medium in light mode</td>
</tr>
<tr>
<td>medium</td>
<td>m</td>
<td>medium in default mode</td>
</tr>
<tr>
<td>semi-bold</td>
<td>sb</td>
<td>bold in light mode</td>
</tr>
<tr>
<td>bold</td>
<td>b</td>
<td>bold in default mode</td>
</tr>
<tr>
<td>semi-bold extended</td>
<td>sbx</td>
<td>bold extended in light mode</td>
</tr>
<tr>
<td>bold extended</td>
<td>bx</td>
<td>bold extended in default mode</td>
</tr>
</tbody>
</table>
In this case, the light option affects only math fonts, the lighttext option is ignored.
This option is not my favorite because the default and light families are cousins but not sisters.
This option affects only roman fonts.

`largesmallcaps` gives larger small capitals than default:
- `LARGE` and `SMALL` (default) small capitals!

`easyscsl` allows you to fit together the commands \textsl and \textsc to get slanted small caps.
- Attention,
  - this option needs the package \texttt{ifthen},
  - to fit together these commands with other fonts produces some errors...

`nofigatures` provides a typesetting without the ff, fi, fl, ffi and ffl ligatures.
- The letter f has a new design to get a good aspect.
The option has no effect with oldstyle or veryoldstyle ones.
You get for instance,"A final effort" instead of,"A final effort".
- And also, "A final effort" instead of, "A final effort".

2.4 New text commands

`\textscsl{...}` and `\scslshape`: provide slanted small caps.

\texttt{Slanted small caps}

\begin{quote}
Obviously, `\textsc{\texttt{...}}` has not the same effect without using the option easyscsl!
\end{quote}

This shape is not usual in \TeX!

`\otherscshape, \textothersc{...}` get the other small caps (default or large) roman or sans-serif.

For instance, you swap between \texttt{small caps text} and \texttt{small caps text}

`\otherscslshape, \textotherscsl{...}` get the other slanted small caps (default or large) roman or sans-serif.
For instance, you swap between

*small caps text*  and  *small caps text*

\otherQ provides the other design of the uppercase letter "Q", with small or large tail.

For instance, you swap between

Question  and  Question

\otherscq, \otherscslq are the same commands for the lowercase small capitals "q".

For instance, you swap between

question  and  question

*The "other" commands change the size of the small caps and the "othertail" commands change the design of the letters "Q"*

In some cases, the section headers for instance, the "other" commands have to be protected: 
"\protect\...other..."!

2.5 Math modes

There are six math modes relative to the command \mathversion.

For instance,

\mathversion{sf}$\left(a+b\right)^2$ gives: \((a+b)^2\)

**normal:** Default mode corresponding to the used options.

**bold:** Bold default mode.

**sf:** The math mode using the sans-serif slanted fonts.

\[ \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6} \]

**boldsf:** Corresponding bold mode.

\[ \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6} \]

**rm:** The usual math mode using the italic roman fonts.

\[ \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6} \]
boldrm: Corresponding bold mode.

\[
\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}
\]

With the \textit{sf} math versions, the option \texttt{widermath} is ignored, as the option \texttt{lightmath}, or, \texttt{light} in math typesetting!

We have also to note there is a new math alphabet \texttt{\textup{mathupright}} or \texttt{\textup{mathup}}. It's equivalent to

- \texttt{\textup{mathrm}} with the \textit{rm} math versions, and,
- \texttt{\textup{mathsf}} with the \textit{sf} math versions.

In another way, it's provide the upright alphabet corresponding to math letters.

2.6 Math typesetting options

\texttt{lighttext}: "light" fonts are used in math mode.

\texttt{sfmath}: the default math mode using the sans-serif slanted fonts, default and \textit{bold}.

Then, you can use the package \texttt{bm} with sans-serif math typesetting;

\texttt{sfmathbb}: in all cases, the \texttt{\textup{mathbb}} font is sans-serif: \texttt{CKNQRZ};

\texttt{rmmathbb}: in all cases, the \texttt{\mathbb} font is roman: \texttt{CKNQRZ};

\texttt{nomathscript}: Kp-Fonts doesn't install the \texttt{\textup{mathrsfs}} command; you need it if you use \texttt{\textup{mathrsfs}} package;

\texttt{mathcalasscript}: swaps the \texttt{\mathcal} and \texttt{\mathscr} fonts;

\texttt{classicReIm}: the \texttt{\textup{Re}} and \texttt{\textup{Im}} commands produce \texttt{R} and \texttt{I}. In default of, Kp-Fonts provides \texttt{Re} and \texttt{Im};

\texttt{uprightRoman}: the \textit{Uppercase} romans are upright.

\texttt{frenchstyle}: equivalent to both the options \texttt{uprightRoman}

and \texttt{uprightgreek}, uppercase romans and lowercase greeks are upright, usual French style when typesetting mathematics; lowercase romans remain slanted;

\texttt{upright}: synonymous with the previous option;
oldstylenumsmath: provides the oldstyle numbers in default and changes the \textstyle, \mathsf and \texttt fonts; they run as text fonts with oldstylenums option;

oldstylemath: provides the oldstyle numbers in default and changes the \textstyle, \mathsf and \texttt fonts; they run as text fonts with oldstyle option;

veryoldstylemath: same as oldstylemath except the round "s" is replaced with the long "f";

narrowiints: provides narrower multiple integral symbols: \int_a^b f(t) instead of \int_a^b f(t)

partialup: provides upright design of the \partial symbol: \partial instead of \partial

You got also the absolute commands \partialup and \partialsl

widermath: with wider space between mathematic letters;

noDcommand: for compatibility with some other package, kpfont doesn’t load the command \D.

Note that, when using the oldstylenumsmath, oldstylemath, veryoldstylemath, fulloldstylenums, fulloldstyle or fullveryoldstyle options, in math mode, as the numbers 3, 4, 5, 7 et 9 have a depth, superscripts are moved up.

2.7 Position of subscripts and superscripts

In math mode, just about with amsmath, the next options adjust the position of subscripts and superscripts.

2.7.1 Integral symbols

The default option is nointlimits.

<table>
<thead>
<tr>
<th>\textstyle</th>
<th>intlimits</th>
<th>nointlimits</th>
<th>fullintlimits</th>
</tr>
</thead>
<tbody>
<tr>
<td>textstyle</td>
<td>$\int_a^b f(t)$</td>
<td>$\int_a^b f(t)$</td>
<td>$\int_a^b f(t)$</td>
</tr>
<tr>
<td>displaystyle</td>
<td>$\int_a^b f(t)$</td>
<td>$\int_a^b f(t)$</td>
<td>$\int_a^b f(t)$</td>
</tr>
</tbody>
</table>
2.7.2 Sums and products

The default option is `sumlimits`.

\[
\begin{array}{|c|c|c|c|}
\hline
\text{\textbackslash sum\_\{i=1\}\textbackslash^\textbackslash n\textbackslash u\_n} & \text{sumlimits} & \text{nosumlimits} & \text{fullsumlimits} \\
\hline
\text{textstyle} & \sum_{i=1}^{n} u_n & \sum_{i=1}^{n} u_n & \sum_{i=1}^{n} u_n \\
\text{displaystyle} & \displaystyle\sum_{i=1}^{n} u_n & \sum_{i=1}^{n} u_n & \sum_{i=1}^{n} u_n \\
\hline
\end{array}
\]

2.8 Greek letters in math mode, options

**uprightgreeks:** lowercase greeks are upright, \(\alpha\beta\gamma\);

**slantedGreeks:** Uppercase greeks are slanted, \(\Gamma\Delta\).

3 Use

3.1 Greek letters

We have described above the two options that alter the default greek letters. Otherwise, you can get the other greek letters using commands like \textbackslash\other\alpha\ or \textbackslash\other\Gamma\. The result depends on the used options.

What’s more, for uppercase, you can use \textbackslash\var\Gamma\ synonymous with the previous.

Finally, the \textbackslash\alpha\sl, \textbackslash\alpha\up, \textbackslash\Gamma\up or \textbackslash\Gammasl commands always give you the letter you want, whatever the chosen options…

3.2 Standard symbols

All the standard symbols are present, including all the symbols of the \textbackslash amssymb package, all with regular and bold weight.

For instance: the standard symbols \(\leq\), \(\pm\), \(\Rightarrow\) or \textbackslash\ams\ symbols \(\rightarrow\) \(\subseteq\) \(\leq\) and in bold: \(\leq\), \(\pm\), \(\Rightarrow\) \(\subseteq\) \(\leq\).

Obviously, you get the usual constructions, both regular and bold: \(\mapsto\mapsto\mapsto\mapsto\).

3.3 Extra symbols

Kp-Fonts provides a lot of other symbols and a lot of negative symbols not displayed here.
\textbf{You can combine these last two symbols:}
\begin{align*}
\textbackslash leadsto & \leadstoext \leadstoext \leadstoext \leadsto \\
\textbackslash boxright & \Diamondright \\
\textbackslash circleright & \Diamondright \\
\textbackslash Diamondleft & \Diamondright \\
\textbackslash boxdotright & \Diamondright \\
\textbackslash circleddotright & \Diamondright \\
\textbackslash Diamondddotleft & \Diamondright \\
\textbackslash DiamondRight & \Diamondright \\
\textbackslash Diamonddashright & \Diamondright \\
\textbackslash multimap & \multimap
\end{align*}
\[ \int f(t) \, dt \]

Kp-Fonts provides variant commands to avoid this. The first is the \texttt{\textbackslash \textbackslash variant} command and you get:

\[ \int f(t) \, dt \]

It is up to you to choose whichever you prefer!
Obviously, this command is not convenient for computing an integral. You can also use $\texttt{\textbackslash D\{\ldots\}}$, the integrate symbol "d" command with best spacing:

\begin{verbatim}
\texttt{displaystyle\varint f(t)\textbackslash D\{t\} \quad \text{gives} \quad \int f(t) \, dt}
\end{verbatim}

With the \texttt{frenchstyle} option, you get an upright "d", like above.

Others variant commands are:
\begin{verbatim}
\variiint, \variiiint, \variiiiint \text{et} \varidotsint.
\end{verbatim}

### 3.5 New extensive symbols

First, the \texttt{\widehat} et \texttt{\widetilde} commands have been extended:

\begin{verbatim}
\texttt{\tilde} \quad \texttt{\chapeau}
\end{verbatim}

You get also th extensive \texttt{\widearc}, \texttt{\widearcarrow} (ou \texttt{\wideOarc}), \texttt{\wideparen} and \texttt{\widering}:

\begin{verbatim}
\texttt{\arc} \quad \texttt{\arrow} \quad \texttt{\paren} \quad \texttt{\RING}
\end{verbatim}

This last command makes an error with the option \texttt{noamsmath}

Finally, some new symbols:

\begin{verbatim}
\bignplus \quad \bigcap \quad \bigcup \quad \bigcupplus \quad \bigsqcupplus \quad \bigsqcapplus \quad \bigsqcup \quad \bigsqcap \quad \varprod
\end{verbatim}

### 3.6 More integrate symbols

There are many unusual integrate symbols:
\oiint \ointctrclockwise \ointclockwise \idotsint \ointclockwise \ointctrclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise \ointclockwise

4 Installation

• With MikTeX, install the package as described here:

http://docs.miktex.org/manual/pkgmgt.html#id562117

• With other distribution, or to install manually with MikTeX, follow these instructions:

1. The tree provides a standard \tds. You have to copy all the files in one of your local \texttt{texmf} trees first and then update your database files.

2. Now, you have to deal with the .map file.

   – If you have a \texttt{web2c} distribution, just run \texttt{updmap}:
     
     \texttt{updmap --enable Map=kpfonts.map}
     
     and/or, this time as \texttt{root}:
     
     \texttt{updmap-sys --enable Map=kpfonts.map}
   
   – With MikTeX, follow the instructions of the manual:
     
     http://docs.miktex.org/manual/advanced.html#psfonts
5 Some extra points

5.1 The Johannes Kepler-project text families

If you want, or if you have to use the low-level commands, the names of
the families are:

<table>
<thead>
<tr>
<th>Font Family</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Roman</td>
<td>jkp[l,x][k][f][osn,os,vos]</td>
</tr>
<tr>
<td>Sans Serif</td>
<td>jkpss[k][f][osn,os,vos]</td>
</tr>
<tr>
<td>Teletype</td>
<td>jkptt[osn,os,vos]</td>
</tr>
</tbody>
</table>

with the relative options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>l, x</td>
<td>light, rmx</td>
</tr>
<tr>
<td>k</td>
<td>largesmallcaps</td>
</tr>
<tr>
<td>f</td>
<td>nofligatures</td>
</tr>
<tr>
<td>osn, os, vos</td>
<td>oldstilenums, oldstyle, veryoldstyle</td>
</tr>
</tbody>
</table>

Obviously, you can’t have f and os or vos.
Note that all the families support ot1, t1 and ts1 encodings.

5.2 Metrics and compatibility

• The light option does not change any metric;

• The oldstilenums or oldstyle options do not change any horizontal metric;

• The veryoldstyle family options change the metrics of the lowercase ‘s’
and the height of the superscripts in math mode;

• There is a full compatibility of the options, except if it is a nonsense,
like both the nomath and frenchstyle options;

• In case of conflict between oldstilenums, oldstyle and veryoldstyle family options, the lighter options are ignored.
5.3 Displaying and printing

Often, some display and printing problems exist...
The main reason is an automatic hinting. I’m not a professional typographer
and I can’t do better; besides, there are some printing problems with old
releases of _Acroread_® using _Windows_®.
Note that the printing is better using _Ghostscript-Ghostview_®...
With the _light_ option, the print is better than display!

5.4 Abstract

You get almost all the features of _kpfonts_ in one page with the file

_kpfonts-abstract.pdf_

5.5 Searching a word

With the _veryoldstyle_ options, the browsers don’t find the rare ligatures si, sl, st and the sacute, scaron and scedilla.

_Don’t use this option if you want to search these words!_

5.6 My favorite options

- For text-only document, I use the _light_ and _oldstyle_ options;
- and for text and math document, I use the _light, frenchstyle, narrowints_ and _partialup_ options, but I’m french!

5.7 Johannes Kepler 1571-1630

Kepler was forced, due to the counter Reformation and because he was
a Lutheran, to move to Prague to work with the renowned Danish astronomer, _Tycho Brahe_. Using the data that Tycho had collected, Kepler discovered the first two laws of planetary motion (1609). And what is just as important about this work is that it is the first published account wherein a scientist documents shows how he has coped with the multitude of imperfect data to forge a theory of surpassing accuracy” (O. Gingerich in foreword to _Johannes Kepler New Astronomy_ translated by W. Donahue, Cambridge Univ Press, 1992), in other words a fundamental law of nature. Today we call this the scientific method.
From nasa website
http://kepler.nasa.gov/johannes/
5.8 Remark

Note that Kepler® is a registered font name supplied by Adobe™. The Kp-Fonts have nothing to do with those.

5.9 Thanks

Many thanks to

- Nicolas Boulanguez (Tests);
- Michel Bovani (Fonts);
- Daniel Flipo (\LaTeX);
- Souraya Muhidine (Translation reviewing)
- Peter Rosenberg (urw)
- Christian Tellechea (package xstring)
- and the contributors of comp.text.tex and fr.comp.text.tex
