1 \textbf{l3draw documentation}

The \texttt{l3draw} package provides a set of tools for creating (vector) drawings in expl3. It is heavily inspired by the \texttt{pgf} layer of the Ti\textsc{k}Z system, with many of the interfaces having the same form. However, the code provided here is build entirely on core expl3 ideas and uses the \texttt{L\textsc{A}TEX3} FPU for numerical support.

Numerical expressions in \texttt{l3draw} are handled as floating point expressions, unless otherwise noted. This means that they may contain or omit explicit units. Where units are omitted, they will automatically be taken as given in (\TeX{}) points.

The code here is \textit{highly} experimental.

\texttt{E-mail: latex-team@latex-project.org}
1.1 Drawings

Each drawing should be created within a \draw_begin:/\draw_end: function pair. The begin function sets up a number of key data structures for the rest of the functions here: unless otherwise specified, use of \draw... functions outside of this “environment” is not supported.

The drawing created within the environment will be inserted into the typesetting stream by the \draw_end: function, which will switch out of vertical mode if required.

\dim_new:N \l_mypos_dim
\draw_begin:
  \draw_path_moveto:n { 0cm , \l_mypos_dim }
  \draw_path_lineto:n { 1cm , \l_mypos_dim }
  \dim_set:Nn \l_mypos_dim { 1cm }
  \draw_path_lineto:n { 1cm , \l_mypos_dim }
  \draw_path_close:
  \draw_path_use_clear:n { stroke }
\draw_end:

Within a drawing, the only commands that should appear are those directly aimed at drawing (from \l3draw) and those which produce no typeset output. For example, it is possible to include loops inside a drawing using \int_step_function:nnnn or similar. On the other hand, text should not be included directly in drawings, but should rather be inserted using the appropriate \l3draw command.

The drawing environment sets the following standard behaviors

- Non-zero rule for fill overlaps
- Butt caps for lines
- Mitering for line joins with a miter factor of 10
- Solid line strokes

Within a drawing, there are different ways of referring to a position. The co-ordinates of a point are given relative to the current drawing axes. These can be manipulated and tracked at the code level. Underlying this is the ⟨canvas⟩, which is at the draw level essentially fixed and in line with the paper. Initially, the two sets of axes are coincident. (It is possible to manipulate the canvas axes at the driver level: this is then “transparent” to the draw level, and so should be used only when strictly required.)

The bounding box of the drawing is determined by tracking the size of the draw commands between the start and end. The bounding box is (roughly) the smallest box that contains all of the co-ordinates mentioned within the drawing. This can include those automatically generated, for example the supporting points needed to construct an arc.
As standard, the baseline of the bounding box of a drawing is calculated automatically at the bottom of the drawing. It is possible to adjust this using the \texttt{\draw_baseline:n} function. If the drawing co-ordinates lead to lower \texttt{y}-axis values than the \texttt{\langle length\rangle}, then the drawing will have a depth as well as a height.

\begin{verbatim}
\draw baseline:n \langle length \rangle
\end{verbatim}

\texttt{\draw_suspend_begin:} Suspends all of the drawing mechanisms to allow “normal” material to be created. Typically, this environment will be applied inside a box which may contain nested pictures.

\begin{verbatim}
\draw_suspend_begin:...
\draw_suspend_end:
\end{verbatim}

This is normal text. More text.
1.2 Graphics state

Within the drawing environment, a number of functions control how drawings will appear. Note that these all apply \textit{globally}, though some are rest at the start of each drawing (\texttt{\textbackslash draw\_begin:}).

\texttt{\textbackslash g\_draw\_linewidth\_default\_dim}

The default value of the linewidth for stokes, set at the start of every drawing (\texttt{\textbackslash draw\_begin:}).

\texttt{\textbackslash draw\_linewidth:n \{\textit{width}\}}

Sets the width to be used for stroking to the \textit{width} (an \texttt{fp expr}).

\texttt{\textbackslash draw\_dash\_pattern:nn \{(pattern)\} \{(phase)\}}

Specifies a dash pattern. The \textit{(pattern)} itself is a comma-separated list of entries which represent the “on” and “off” parts of the line. These are all \texttt{fp expr} and repeat as required. Thus the \textit{(pattern)} may be of arbitrary length. The \textit{(phase)} specifies where during the first “on” line the pattern should start.

\begin{verbatim}
\texttt{\textbackslash draw\_begin:}
    \texttt{\textbackslash draw\_dash\_pattern:nn}
    \{ 0.5cm , 0.5cm , 0.1cm , 0.2cm \}
    \{ 0cm \}
    \texttt{\textbackslash draw\_path\_moveto:n \{ 0cm , 0cm \}}
    \texttt{\textbackslash draw\_path\_lineto:n \{ 2cm , 0cm \}}
    \texttt{\textbackslash draw\_path\_use\_clear:n \{ stroke \}}
    \texttt{\textbackslash draw\_dash\_pattern:nn}
    \{ 0.5cm , 0.5cm , 0.1cm , 0.2cm \}
    \{ 0.1cm \}
    \texttt{\textbackslash draw\_path\_moveto:n \{ 0cm , 1mm \}}
    \texttt{\textbackslash draw\_path\_lineto:n \{ 2cm , 1mm \}}
    \texttt{\textbackslash draw\_path\_use\_clear:n \{ stroke \}}
    \texttt{\textbackslash draw\_dash\_pattern:nn}
    \{ 0.5cm , 0.5cm , 0.1cm , 0.2cm \}
    \{ 0.2cm \}
    \texttt{\textbackslash draw\_path\_moveto:n \{ 0cm , 2mm \}}
    \texttt{\textbackslash draw\_path\_lineto:n \{ 2cm , 2mm \}}
    \texttt{\textbackslash draw\_path\_use\_clear:n \{ stroke \}}
\end{verbatim}

Setting an empty pattern will produce a solid line.

Note the \textit{(pattern)} interface here is different from that in \texttt{pgf}: the list is comma-separated not given in brace groups.

\texttt{\textbackslash draw\_nonzero\_rule:}\texttt{\textbackslash draw\_evenodd\_rule:}

Active either the non-zero winding number or the even-odd rule, respectively, for determining what is inside a fill or clip area. For technical reasons, these command are not influenced by scoping and apply on an ongoing basis.
\draw_cap_butt:
\draw_cap_rectangle:
\draw_cap_round:

Sets the style of terminal stroke position to one of butt, rectangle or round.

\draw_join_bevel:
\draw_join_miter:
\draw_join_round:

\draw_cap_butt:
Sets the style of stroke joins to one of bevel, miter or round.

\draw_miterlimit:n \{\langle factor\rangle\}

Sets the miter \langle factor\rangle of lines joined as a miter, as described in the PDF and PostScript manuals. The \langle factor\rangle is an \langle fp expr\rangle.

1.3 Scoping drawing elements

Scoping drawing elements is necessary to allowing nesting of subparts. These features have specific use requirements: the preconditions must be met. In particular, each type of drawing scope also constitutes a group (\group_begin;/\group_end: pair): as such, they must be nested correctly.
A scope forms a TeX group but will also localise global state variables (such as \texttt{\gdraw_linewidth_default_dim}), and driver-level concepts such as the termination of lines.

Global graphical concepts restricted by scope are

- Line width
- Stroke and fill color
- Dash pattern
- Line joining and capping, including the miter limit
- Clipping paths
- Canvas (driver) transformations

### 1.4 Points

Functions supporting the calculation of points (co-ordinates) are expandable and may be used outside of the drawing environment. The outputs of all of the point functions are tuples. This output form is then suitable as input for subsequent point calculations, \textit{i.e.} where a \texttt{\langle point\rangle} is required it may be given as a tuple. This may include units and surrounding parentheses, for example

1,2
1cm,3pt
(1pt,2cm)
2 * sind(30), 2*4in

are all valid input forms. Notice that each part of the tuple may itself be a float point expression.

Point co-ordinates are relative to the canvas axes, but can be transformed by \texttt{\draw_point_transform:n}. These manipulation is applied by many higher-level functions, for
example path construction, and allows parts of a drawing to be rotated, scaled or skewed. This occurs before writing any data to the driver, and so such manipulations are tracked by the drawing mechanisms. See \backend_cm:nnnn for backend-level manipulation of the canvas axes themselves.

Notice that in contrast to \pgf it is possible to give the positions of points directly.

### 1.4.1 Basic point functions

\draw_point_polar:nn \*
\draw_point_polar:nnn \*

Gives the co-ordinates of the point at \( \langle \text{angle} \rangle \) (an \( \text{fp expr} \) in degrees) and \( \langle \text{radius} \rangle \). The three-argument version accepts two radii of different lengths.

Note the interface here is somewhat different from that in \pgf: the one- and two-radii versions in \l3draw use separate functions, whilst in \pgf they use the same function and a keyword.

\draw_point_unit_vector:n \*
\draw_point_unit_vector:n \*

Expands to the co-ordinates of a unit vector in the direction of the \( \langle \text{point} \rangle \) from the origin. If the \( \langle \text{point} \rangle \) is at the origin, a vertical unit vector is returned.

\draw_point_transform:n \*
\draw_point_transform:n \*

Evaluates the position of the \( \langle \text{point} \rangle \) subject to the current transformation matrix. This operation is applied automatically by most higher-level functions (\textit{e.g.} path manipulations).

### 1.4.2 Points on a vector basis

As well as giving explicit values, it is possible to describe points in terms of underlying direction vectors. The latter are initially co-incident with the standard Cartesian axes, but may be altered by the user.

\draw_xvec:n \*
\draw_yvec:n \*
\draw_zvec:n \*

Defines the appropriate base vector to point toward the \( \langle \text{point} \rangle \) on the canvas. The standard settings for the \( x \)- and \( y \)-vectors are 1 cm along the relevant canvas axis, whilst for the \( z \)-vector an appropriate direction is taken.

\draw_point_vec:nn \*
\draw_point_vec:nnn \*

Expands to the co-ordinate of the point at \( \langle \text{yscale} \rangle \) times the \( x \)-vector and \( \langle \text{yscale} \rangle \) times the \( y \)-vector. The three-argument version extends this to include the \( z \)-vector.
\draw_point_vec_polar:nn * \draw_point_vec_polar:nn \{\langle radius\rangle\} \{\langle angle\rangle\}
\draw_point_vec_polar:nn * \draw_point_vec_polar:nn \{\langle radius-a\rangle\} \{\langle radius-b\rangle\} \{\langle angle\rangle\}

Gives the co-ordinates of the point at \langle angle\rangle (an \langle fp\ expr\rangle in degrees) and \langle radius\rangle, relative to the prevailing x- and y-vectors. The three-argument version accepts two radii of different lengths.

Note the interface here is somewhat different from that in \texttt{pgf}: the one- and two-radii versions in \texttt{l3draw} use separate functions, whilst in \texttt{pgf} they use the same function and a keyword.

### 1.4.3 Intersections

\draw_point_intersect_lines:nnnn * \draw_point_intersect_lines:nnnn \{\langle point1\rangle\} \{\langle point2\rangle\} \{\langle point3\rangle\} \{\langle point4\rangle\}

Evaluates the point at the intersection of one line, joining \langle point1\rangle and \langle point2\rangle, and a second line joining \langle point3\rangle and \langle point4\rangle. If the lines do not intersect, or are coincident, and error will occur.

\draw_point_intersect_circles:nnnnn * \draw_point_intersect_circles:nnnnn \{\langle center1\rangle\} \{\langle radius1\rangle\} \{\langle center2\rangle\} \{\langle radius2\rangle\} \{\langle root\rangle\}

Evaluates the point at the intersection of one circle with \langle center1\rangle and \langle radius1\rangle, and a second circle with \langle center2\rangle and \langle radius2\rangle. If the circles do not intersect, or are coincident, and error will occur.

Note the interface here has a different argument ordering from that in \texttt{pgf}, which has the two centers then the two radii.

\draw_point_intersect_line_circle:nnnnn * \draw_point_intersect_line_circle:nnnnn \{\langle point1\rangle\} \{\langle point2\rangle\} \{\langle center\rangle\} \{\langle radius\rangle\} \{\langle root\rangle\}

Evaluates the point at the intersection of one line, joining \langle point1\rangle and \langle point2\rangle, and a circle with \langle center\rangle and \langle radius\rangle. If the lines and circle do not intersect and error will occur.

### 1.4.4 Interpolations

\draw_point_interpolate_line:nnn * \draw_point_interpolate_line:nnn \{\langle part\rangle\} \{\langle point1\rangle\} \{\langle point2\rangle\}

Expands to the point which is \langle part\rangle way along the line joining \langle point1\rangle and \langle point2\rangle. The \langle part\rangle may be an interpolation or an extrapolation, and is a floating point value expressing a percentage along the line, \textit{e.g.} a value of 0.5 would be half-way between the two points.

\draw_point_interpolate_distance:nnn * \draw_point_interpolate_distance:nnn \{\langle distance\rangle\} \{\langle point\ expr1\rangle\} \{\langle point\ expr2\rangle\}

Expands to the point which is \langle distance\rangle way along the line joining \langle point1\rangle and \langle point2\rangle. The \langle distance\rangle may be an interpolation or an extrapolation.
\draw_point_interpolate_curve:nnnnn \<part\> \<start\> \<control1\> \<control2\> \<end\>

Expands to the point which is \<part\> way along the curve between \<start\> and \<end\> and defined by \<control1\> and \<control2\>. The \<part\> may be an interpolation or an extrapolation, and is a floating point value expressing a percentage along the curve, e.g. a value of 0.5 would be half-way along the curve.

1.5 Paths

Paths are constructed by combining one or more operations before applying one or more actions. Thus until a path is “used”, it may be manipulated or indeed discarded entirely. Only one path is active at any one time, and the path is not affected by \TeX{} grouping.
\draw_path_corner_arc:nn \draw_path_corner_arc:nn \{(\text{length1})\} \{(\text{length2})\}

Sets the degree of rounding applied to corners in a path: the two \textit{\texttt{length}} values are the distances from the corner at which the curving should start. The first \textit{\texttt{length}} applies to the part of the path “leading in” to the corner (\textit{i.e.} from the previous path operation), and the second to that “leading out”. If both values are 0pt then corners will not be rounded. The values apply within the scope of the current \TeX{} group.

\begin{verbatim}
\draw_begin:
  \draw_path_corner_arc:nn { 5mm } { 5mm }
  \draw_path_rectangle_corners:nn
    { 0cm , 0cm } { 3cm , 2cm }
  \draw_path_use_clear:n { stroke }
\draw_end:
\end{verbatim}

\begin{verbatim}
\draw_begin:
  \draw_path_corner_arc:nn { 10mm } { 5mm }
  \draw_path_moveto:n { 0cm , 0cm }
  \draw_path_lineto:n { 0cm , 2cm }
  \draw_path_lineto:n { 3cm , 2cm }
  \draw_path_curveto:nnn
    { 3cm , 0cm } { 2cm , 0cm } { 1cm , 0cm }
  \draw_path_use_clear:n { stroke }
\draw_end:
\end{verbatim}

The corners created are quarter-circles for exact right-angles and close approximations otherwise. Closing a path will result in rounding correctly.

\begin{verbatim}
\draw_begin:
  \draw_path_corner_arc:nn { 4pt } { 4pt }
  \draw_path_moveto:n
    { \draw_point_polar:nn { 1cm } { 0 } }
  \int_step_inline:nnnn { 72 } { 72 } { 359 } { 
    \draw_path_lineto:n
      { \draw_point_polar:nn { 1cm } { #1 } }
  }
  \draw_path_close:
  \draw_path_use_clear:n { stroke }
\draw_end:
\end{verbatim}

\draw_path_close: \draw_path_close:

Closes the current part of the path by appending a straight line from the current point to the starting point of the path. In general, any path to be \textit{\texttt{filled}} should include a close instructions.
\draw_path_use:{(action(s))}

Inserts the current path, carrying out one or more possible \textit{actions} (a comma list):

- \textbf{stroke} Draws a line along the current path
- \textbf{draw} A synonym for \textbf{stroke}
- \textbf{fill} Fills the interior of the path with the current file color
- \textbf{clip} Clips any content outside of the path

Actions are applied in the order given irrespective of the input order. Note that whilst it is possible to use a path without clearing it, the normal use case would be to clear the path (this resets data structures at the macro level).

1.5.1 Path operations on drawing axes

The standard path functions are all influenced by the active transformation matrix, \textit{i.e.} the work relative to the drawing axes rather than the canvas.

\draw_path_moveto:{(point)}

Moves the reference point of the path to the \textit{(point)}, but will not join this to any previous point.

\draw_path_lineto:{(point)}

Joins the current path to the \textit{(point)} with a straight line. In general, for reliable treatment by viewers, a \texttt{\draw_path_moveto:n} operation should precede the first use of a \texttt{\draw_path_lineto:n} on a path.

\begin{verbatim}
\draw_begin:
  \draw_path_moveto:n { 0cm , 0cm }
  \draw_path_lineto:n { 1cm , 1cm }
  \draw_path_lineto:n { 2cm , 1cm }
  \draw_path_lineto:n { 3cm , 0.5cm }
  \draw_path_lineto:n { 3cm , 0cm }
  \color_fill:n { yellow!80!black }
  \draw_path_use_clear:n { fill , stroke }
\draw_end:
\end{verbatim}

\begin{verbatim}
\draw_begin:
  \draw_path_moveto:n { 0cm , 0cm }
  \draw_path_lineto:n { 1cm , 1cm }
  \draw_path_lineto:n { 2cm , 1cm }
  \draw_path_lineto:n { 2cm , 1cm } % Begins a new part
  \draw_path_lineto:n { 3cm , 0.5cm }
  \draw_path_lineto:n { 3cm , 0cm }
  \color_fill:n { yellow!80!black }
  \draw_path_use_clear:n { fill , stroke }
\draw_end:
\end{verbatim}
\draw_path_curveto:nn \{ (control1) \} \{ (control2) \} \{ (end) \}

Joins the current path to the (end) with a curved line defined by cubic Bézier points (control1) and (control2). The bounding box of the path (and image) will fully-contain the curve and control points, \textit{i.e.} it may be bigger than strictly necessary to contain the curve \textit{alone}.

\draw_begin:
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_curveto:nnn
{ 1cm , 1cm } \% First control
{ 2cm , 1cm } \% Second control
{ 3cm , 0cm } \% End
\color_fill:n { yellow!80!black }
\draw_path_use_clear:n { fill , stroke }
\draw_end:

\draw_path_curveto:nn \{ (control) \} \{ (end) \}

Joins the current path to the (end) with a curved line defined by quadratic Bézier point (control). The bounding box of the path (and image) will fully-contain the curve and computed (cubic) control points, \textit{i.e.} it may be bigger than strictly necessary to contain the curve \textit{alone}.

\draw_begin:
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_curveto:nn
{ 1cm , 1cm }
{ 2cm , 0cm }
\color_fill:n { yellow!80!black }
\draw_path_use_clear:n { fill , stroke }
\draw_end:
Joins the current path with an arc between \langle angle1 \rangle and \langle angle2 \rangle and of \langle radius \rangle. The four-argument version accepts two radii of different lengths.

\begin{verbatim}
\draw_begin:
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_lineto:n { 0cm , 1cm }
\draw_path_arc:nnn { 180 } { 90 } { 0.5cm }
\draw_path_lineto:n { 3cm , 1.5cm }
\draw_path_arc:nnnn { 90 } { -45 } { 0.5cm } { 0cm }
\draw_path_use_clear:n { fill }
\draw_end:
\end{verbatim}

Note the interface here has a different argument ordering from that in pgf, which has the two centers then the two radii.

\begin{verbatim}
\draw_begin:
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_arc:nnnn { 180 } { 45 } { 2cm } { 1cm }
\draw_path_use_clear:n { stroke }
\draw_end:
\end{verbatim}

Appends the portion of an ellipse from \langle angle1 \rangle to \langle angle2 \rangle of an ellipse with axes along \langle vector1 \rangle and \langle vector2 \rangle to the current path.

\begin{verbatim}
\draw_begin:
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_lineto:n { 2cm , 5mm }
\draw_path_moveto:n { 0cm , 0cm }
\draw_path_lineto:n { 0cm , 1cm }
\draw_path_moveto:n { 2cm , 5mm }
\draw_path_arc_axes:nnnn { 0 } { 90 } { 2cm , 5mm } { 0cm , 1cm }
\draw_path_use_clear:n { stroke }
\draw_end:
\end{verbatim}
\texttt{\textbackslash draw\_path\_ellipse:nnn} \texttt{\{\textit{center}\}} \texttt{\} \texttt{\{\textit{vector1}\}} \texttt{\} \texttt{\{\textit{vector2}\}}

Appends an ellipse at \texttt{\{\textit{center}\}} with axes along \texttt{\{\textit{vector1}\}} and \texttt{\{\textit{vector2}\}} to the current path. A new part is started if the path is already non-empty. Notice that the underlying drawing is constructed from arcs with appropriate moves: the interfaces is a more efficient convenience.

\begin{verbatim}
\draw_begin:
 \draw_path_ellipse:nnn 
 \{ 1cm , 0cm \}
 \{ 1.5cm , 0cm \}
 \{ 0cm , 1cm \}
 \draw_path_use_clear:n \{ stroke \}
 \color_select:n \{ red \}
 \draw_path_ellipse:nnn 
 \{ 1cm , 0cm \}
 \{ 1cm , 1cm \}
 \{ -0.5cm , 0.5cm \}
 \draw_path_use_clear:n \{ stroke \}
 \draw_end:
\end{verbatim}

Note that any transformation is applied to the completed ellipse rather than to the axes.

\texttt{\textbackslash draw\_path\_circle:nn} \texttt{\{\textit{center}\}} \texttt{\{\textit{radius}\}}

Appends a circle of \texttt{\{\textit{radius}\}} at \texttt{\{\textit{center}\}} to the current path. This is a shortcut for \texttt{\textbackslash draw\_path\_ellipse:nnn}.

\begin{verbatim}
\draw_path_rectangle:nn 
\{ 1cm , 0cm \}
\{ 1.5cm , 1cm \}
\draw_path_rectangle:nn 
\{ 1.5cm , 0.25cm \}
\{ 1.5cm , 1cm \}
\draw_path_rectangle:nn 
\{ 2cm , 0.5cm \}
\{ 1.5cm , 1cm \}
\draw_path_use_clear:n \{ draw \}
\draw_end:
\end{verbatim}

\begin{verbatim}
\draw_begin:
 \draw_path_rectangle_corners:nn 
\{ 1cm , 0cm \}
\{ 1.5cm , 1cm \}
\draw_path_use_clear:n \{ draw \}
\draw_end:
\end{verbatim}
\draw_path_grid:nnnn \{(xstep)\} \{(ystep)\} \{(lower-left)\} \{(upper-right)\}

Constructs a grid of \((xstep)\) and \((ystep)\) inside the rectangle defined by the \((lower-left)\) and the \((upper-right)\), and appends this to the current path. The grid will be aligned such that grid lines pass through the origin, which may result in “protruding” ends if the start/end positions do not fully align.

\draw_begin:
\draw_linewidth:n \{ 0.8pt \}
\draw_path_grid:nnnn 
\{ 1cm \} \{ 1cm \}
\{ -3mm , -3mm \}
\{ 33mm , 23mm \}
\draw_path_use_clear:n \{ stroke \}
\draw_linewidth:n \{ 0.4pt \}
\draw_path_grid:nnnn 
\{ 1mm \} \{ 1mm \}
\{ -1.5mm , -1.5mm \}
\{ 31.5mm , 21.5mm \}
\draw_path_use_clear:n \{ stroke \}
\draw_end:

Any transformation is applied to the finished grid.

\draw_begin:
\draw_transform_rotate:n \{ 10 \}
\draw_path_grid:nnnn 
\{ 1mm \} \{ 2mm \}
\{ 0mm , 0mm \}
\{ 30mm , 30mm \}
\draw_path_use_clear:n \{ stroke \}
\draw_end:

1.5.2 Path scope

\draw_path_scope_begin: \draw_path_scope_end:

Suspended (and saves) the current (partial) path, initialising a new path within the scope. Path operations are written to output only when used, so the scoped path is stored at the expl3 level, not in the output.

1.5.3 Path operations on canvas axes

For specialist work, a small number of functions are provided which work relative to the canvas axes, i.e. these functions ignore the transformation matrix.

\draw_path_canvas_moveto:n \{(canvas point)\}

Moves the reference point of the path to the \((canvas point)\), but will not join this to any previous point.
\draw_path_canvas_lineto:n \{\text{canvas point}\}
Joins the current path to the \{\text{canvas point}\} with a straight line.

\draw_path_canvas_curveto:nnn \{\text{control1}\} \{\text{control2}\} \{\text{end}\}
Joins the current path to the \{\text{end}\} with a curved line defined by cubic Bézier points \{\text{control1}\} and \{\text{control2}\}. These positions are given as canvas points.

1.6 Bounding box

\l_draw_bb_update_bool
All functions automatically update the bounding box of the image, unless specified otherwise. This behavior is selectable using the \l_draw_bb_update_bool boolean.

1.7 Boxes and coffins

\draw_box_use:N \{\text{box}\}
Inserts the \{\text{box}\} into a drawing, taking account of the current transformation matrix and shift, and adjusting the drawing bounding box to contain the (apparent) size of the box if this is active (see \l_draw_bb_update_bool).

\draw_begin:
\draw_path_moveto:n \{0cm, 0cm\}
\draw_path_lineto:n \{0cm, 1cm\}
\draw_path_use_clear:n \{\text{stroke}\}
\hbox_set:Nn \l_tmpa_box { This is text. }
\draw_box_use:N \l_tmpa_box
\draw_end:

This is text.

\draw_begin:
\draw_transform_matrix_absolute:nnnn \{2\} \{0\} \{1\} \{2\}
\draw_path_moveto:n \{0cm, 0cm\}
\draw_path_lineto:n \{0cm, 1cm\}
\draw_path_use_clear:n \{\text{stroke}\}
\hbox_set:Nn \l_tmpa_box { This is text. }
\draw_box_use:N \l_tmpa_box
\draw_end:

\draw_begin:
\draw_transform_matrix_absolute:nnnn \{2\} \{0\} \{1\} \{2\}
\draw_path_moveto:n \{0cm, 0cm\}
\draw_path_lineto:n \{0cm, 1cm\}
\draw_path_use_clear:n \{\text{stroke}\}
\hbox_set:Nn \l_tmpa_box { This is text. }
\draw_box_use:N \l_tmpa_box
\draw_end:

\draw_begin:
\draw_transform_matrix_absolute:nnnn \{2\} \{0\} \{1\} \{2\}
\draw_path_moveto:n \{0cm, 0cm\}
\draw_path_lineto:n \{0cm, 1cm\}
\draw_path_use_clear:n \{\text{stroke}\}
\hbox_set:Nn \l_tmpa_box { This is text. }

\draw_coffin_use:Nn \draw_coffin_use:N \{\text{coffin}\} \{\langle \text{hpole} \rangle\} \{\langle \text{vpole} \rangle\}

Inserts the \langle \text{coffin} \rangle into a drawing, taking account of the current transformation matrix and shift, and adjusting the drawing bounding box to contain the (apparent) size of the box if this is active (see \l_draw_bb_update_bool). The alignment point of the coffin to the origin is specified by the intersection of the \langle \text{hpole} \rangle and the \langle \text{vpole} \rangle.

1.8 Transformations
Points are normally used unchanged relative to the canvas axes. This can be modified by applying a transformation matrix. The canvas axes themselves may be adjusted using \driver_draw_cm:nnnn: note that this is transparent to the drawing code so is not tracked.

\draw_transform_matrix:nnnn \draw_transform_matrix:nnnn \{\langle a\rangle\} \{\langle b\rangle\} \{\langle c\rangle\} \{\langle d\rangle\}

Applies the transformation matrix \[[\langle a\rangle\langle b\rangle\langle c\rangle\langle d\rangle]\]. The basic applies the transformation in addition to those active; the absolute version overwrites any active transformation. This assignment is local.

\draw_transform_shift:n \draw_transform_shift:n \draw_transform_shift_absolute:n
\draw_transform_shift:n \{\langle \text{vector} \rangle\}

Applies the transformation \langle \text{vector} \rangle to points. The basic applies the vector in addition to those active; the absolute version overwrites any active vector. This assignment is local.

\draw_transform_triangle:nnn \draw_transform_triangle:nnn \{\langle \text{origin} \rangle\} \{\langle \text{point1} \rangle\} \{\langle \text{point2} \rangle\}

Applies a transformation such that the co-ordinates \((0,0)\), \((1,0)\) and \((0,1)\) are given by the \langle \text{origin} \rangle, \langle \text{point1} \rangle and \langle \text{point2} \rangle, respectively. This assignment is local.

\draw_transform_rotate:n \draw_transform_rotate:n \{\langle \text{angle} \rangle\}

Applies a rotation by the \langle \text{angle} \rangle, measured anti-clockwise in degrees. This rotation is additional to any prevailing transformation. This assignment is local.

\draw_transform_scale:n \draw_transform_scale:n \draw_transform_xscale:n \draw_transform_yscale:n \{\langle \text{scale} \rangle\}

Applies the \langle \text{scale} \rangle in either \text{x} or \text{y} (or both). This scale is added to any prevailing transformation. This assignment is local.
\draw_transform_xshift:n \draw_transform_xslant:n \draw_transform_matrix_invert: \draw_transform_matrix_reset: \draw_transform_shift_invert: \draw_transform_shift_reset: 

Applies an \((xshift)\) or \((yshift)\), as appropriate. This shift is \textit{added} to any prevailing one. This assignment is local.

\draw_transform_xslant:n \draw_transform_yslant:n \draw_transform_matrix_invert: \draw_transform_matrix_reset: \draw_transform_shift_invert: \draw_transform_shift_reset: 

Applies the \((slant)\) (a factor) in either \(x\) or \(y\). This slant is \textit{added} to any prevailing transformation. This assignment is local.

\draw_transform_matrix_invert: \draw_transform_matrix_reset: \draw_transform_shift_invert: \draw_transform_shift_reset: 

Inverts the current transformation matrix or shift vector, as appropriate. This assignment is local.

\draw_transform_matrix_invert: \draw_transform_matrix_reset: \draw_transform_shift_invert: \draw_transform_shift_reset: 

Resets the current transformation matrix or shift vector, as appropriate. This assignment is local.

\draw_layer_new:n \draw_layer_begin:n \draw_layer_end: \l_draw_layers_clist

1.9 Layers

Drawing layers may be used to alter the way in which elements are stacked on top of one another. In particular, they are useful when the nature of an element depends on another, but where it needs to be behind it’s “parent”. A classic example is a filled background: this needs to know the size of the material it is behind.

All drawings feature a layer called \texttt{main}. This layer should always be present, and is the one which “non-layered” content is added to.

\draw_layer_new:n \draw_layer_begin:n \draw_layer_end: \l_draw_layers_clist

The list of active layers: may be given anywhere before \draw_end:. The \texttt{main} layer should always be included.

Index

The italic numbers denote the pages where the corresponding entry is described, numbers underlined point to the definition, all others indicate the places where it is used.
